& E_{r l s}(w, n, p):=\frac{c e^{2}}{4 \cdot \pi \cdot \varepsilon \cdot r(w, n, p)}-(m q(w, n, p) \cdot(\beta(n, p)-1)) \cdot c^{2} \\
& \text { p:= 1, 2 .. } 140
\end{aligned}
$$

Note that at the maximum attainable $p$ value (about 120), the radius has dropped to well below 4 fm . Muonic fusion occurs at a distance of about 250 fm , which equates to a $p$ value of 14-15. Consequently it would seem it ought to be reasonably easy to facilitate fusion through shrunken hydrogen.

## Example:-

p := 1,2.. 10
$E p_{p}:=E_{r l s}(2,1, p)$

$E p=$|  | 0 |
| :--- | :--- |
| 0 | 0 |
| 1 | 13.598 |
| 2 | 54.39 |
| 3 | 122.37 |
| 4 | 217.526 |
| 5 | 339.844 |
| 6 | 489.304 |
| 7 | 665.881 |
| 8 | 869.549 |
| 9 | $1.1 \cdot 10^{3}$ |
| 10 | $1.358 \cdot 10^{3}$ |
